Abstract - Text classification and feature selection plays an important role for correctly identifying the documents into particular category, due to the explosive growth of the textual information from the electronic digital documents as well as world wide web. In the text mining present challenge is to select important or relevant feature from large and vast amount of features in the data set. The aim of this paper is to improve the feature selection method for text document classification in machine learning. In machine learning the training set is generated for testing the documents. This can be achieved by selecting important new term i.e. weights of term in text document to improve both classification with relevance to accuracy and performance.

Keywords - Text classification, Feature selection.

I. INTRODUCTION

With the rapid growth of the world wide web and data in digital format, the task of automatic document classification is important for organization. The information and knowledge discovery from documents are done manually in many companies. Proper classification of electronic documents, online news, blogs, e-mails and digital libraries requires Text Mining, Machine leaning and natural language processing techniques to extract required knowledge information. Text mining makes an attempt to discover interesting information and knowledge from unstructured documents. The important task is to develop the automatic classifier to maximize the accuracy and efficiency to classify the existing and incoming documents.

In reality a large portion of the available information does not appear in structured databases but rather in collections of text articles drawn from various sources. Unstructured information refers to computerized information that either does not have a data model or the one that is not easily used by a computer program. The term distinguishes such information from data stored in field form in databases or annotated in documents. However, data mining deals with structured data, whereas text presents special characteristics and is unstructured. The important task is how these documented data can be properly retrieved, presented and classified. Extraction, integration and classification of electronic documents from different sources and knowledge information discovery from these documents are important.

In data mining, Machine learning is often used for Prediction or Classification. Classification involves finding rule that partition the data into disjoint groups. The input for the classification is the training data set, whose class labels are already known. Classifications analyze the training data set and construct a model based on the class label. The goal of classification is to build a set of models that can correctly predict the class of the different objects. Machine learning is an area of artificial intelligence concerned with the development of techniques which allow computers to "learn". More specifically, machine learning is a method for creating computer programs by the analysis of data sets since machine learning study the analysis of data. The challenging task is of text classification performance, because many problems are due to high dimensionality of feature space and unordered collection of words in text documents. This paper will mainly focus on implementation of the text document feature selection.

‘Bag of words’ [1] is the simplest representation of textual data. Vector space model (VSM)[2] is widely used in document classification system. Thousands of term word occurs in the text document, so it is important to reduce the dimensionality of feature using feature selection process [3], to resolve this problem different techniques can be used. Researchers have used different feature selection methods such as X2 Statistics (CHI), Information Gain (IG), mutual information, term strength, document frequency. With the help of these approaches it is possible to reduce the high dimensionality of features. Proposed IDFDDF (Inverse Document Frequency Divide Document Frequency) is the most effective method to reduce the dimensionality of feature space and improve the efficiency and accuracy of classifier. In this approach document preprocessing is also important to reduce the complexity and high dimensionality of term words occurs in the text document.

II. DOCUMENT REPRESENTATION

One of the pre-processing techniques is the document representation which is used to reduce the complexity of the documents. The documents need to be transformed from the full text version to a document vector. Text classification is again an important component in most information management tasks for which algorithms that can maintain high accuracy are desired. Dimensionality reduction is a very important step in text classification, because irrelevant and redundant features often degrade the performance of classification both in speed and classification accuracy. Dimensionality reduction technique can be classified into feature extraction (FE) [4] and feature selection (FS) approaches given below.

IJRITCC | September 2014, Available @ http://www.ijritcc.org
A. Feature Extraction

FE is the first step of pre-processing which is used to present the text documents into clear word format. So removing stop words and stemming words is the pre-processing tasks [5] [6]. The documents in text classification are represented by a great amount of features and most of them could be irrelevant or noisy [7]. DR is the exclusion of a large number of keywords, base preferably on a statistical process, to create a low dimension vector [8]. Commonly the steps taken for the feature extractions (Fig.1) are:

Tokenization: A document is treated as a string, and then partitioned into a list of tokens.
Removing stop words: Stop words such as “the”, “a”, “and”... etc are frequently occurring, so the insignificant words need to be removed.
Stemming word: Applying the stemming algorithm that converts different word form into similar canonical form. This step is the process of conflating tokens to their root form, e.g. connection to connect, computing to compute etc.

III. FEATURE SELECTION APPROACHES

Feature selection helps in the problem of text classification to improve efficiency and accuracy. In our approach we are examining different feature selection methods and then will find whether our proposed method is effective to other studied method.

A. TF (Term Frequency)

Term frequency in the given document is simply the number of times a given term appears in that document. TF used to measure the importance of item in a document, the number of occurrences of each term in the document. Every document is described as a vector consisting of words such as

\[
D = \langle \text{Term}_1, \text{Term}_2, \ldots, \text{Term}_n \rangle
\]

Where D means the Document and Term means the word on that document and n represents the number of words in the document.

Importance of the term’t’ within the particular document with “ni” being the number of occurrences of the considered term and the denominator is the number of occurrences of all terms.

\[
TF = \sum_{k}^{n} \frac{n_i}{n_k}
\]

B. DF (Document Frequency)

One way of calculating the document frequency (DF) is to determine how many documents contain the term’t’ divide by the total number of documents in the collection. |D| is the total no of documents in the document set D, and \(|\{di \, tj \in di \in D\}|\) is the number of documents containing term \(tj\).

C. IDF (Inverse Document Frequency)

The inverse document frequency is a measure of the general importance of the term in the corpus. It assigns smaller value to the words occurring in the most of the documents and higher values to those occurring in fewer documents. It is the logarithm of the number of all documents divided by the number of documents containing the term.

\[
IDF = \log \frac{|D|}{|\{di \, tj \in di \in D\}|}
\]

OR

\[
IDF = \log \frac{|D|}{|\{di \, tj \in D\}|}
\]
Where \(|D|\) is total no of documents in the corpus & \(|\{di \Rightarrow ti\}|\) is number of documents where the term ‘ti’ appears.

D. Our Approach : IDFDDF (Inverse Document Frequency Divide by Document Frequency)

Using the inverse document frequency and document frequency it is the division of IDF and DF, it is denoted as IDFDDF.

\[
\text{IDFDDF} = \log \left( \frac{|D|}{|\{di \in D\}|} \right)
\]

TFIDF is commonly used to represent term weight numerically using multiplication of term frequency and inverse document frequency [11]. IDFDDF is commonly used to represent inverse document frequency divided by document frequency. Here we can also get the numerical value and assign to the related term. Using these we can select the relevant (important) term from the total number of features in the corpus. The proposed method of feature selection is described as follows.

Step1: Collect the different Data sets.
Step2: Text tokenization:
1. Its conversion is very important for separating the sentences into words.
2. Produce the sequence of term features of document.
3. Remove all non-alphanumeric characters then convert into word string.

Step3: Filtration:
First these words are converted into lower case
Remove all stop words using already well defined Blockade list.

Step4: Stemming:
In this process system removes the word’s prefixes and suffixes. Applying stemming algorithm or own method.

Step5: We get the highly relevant words from the document.

Step6: All the terms and frequencies are collected from each document. Evaluate and retain values of TF.

Step7: Repeat Step2 to Step6 for all the documents of corpus.

Step8: Evaluate and retain all values of DF, IDF, and IDFDDF.

Step9: Obtain the word feature set of corpus.

IV. EXPERIMENTAL RESULTS

To evaluate the performance of our proposed method we have perform experiment on data set R8 of Reuters 21578. The experiment have been performed on Pentium® Dual-Core CPU, 3GB RAM, Windows Vista 32-bit Operating System, and MATLABR2008a. Table 1 shows the detailed information of the data set. Performance of our proposed method using above mention dataset is shown in Figure 2.

To reduce the dimensionality of original text documents using preprocessing step, the documents are converted into the vectors after which removes the non-alphanumeric characters and then insignificant words (keywords) called as filtration process hence removes the noisy elements from the term vector. After removal of noisy elements perform stemming process which is important for the text document feature selection. In this process remove the lexicons i.e. s, es, ing, ed, est etc. This process can be executed using our own method for lexicon removal instead of any existing algorithms. Stemming process generates the different word in single form in which we get the original term features of the corpus. Using traditional document frequency and inverse document frequency algorithm calculates the numeric values for the term feature of the corpus. With the help of these values proposed IDFDDF method is used to generate new numerical values for the corresponding term. These term values are ordered by their IDFDDF values in descending order. For creating the training set for testing the corpus documents, conduct feature selection by picking up top few terms. It has been observed that using top most minimum terms related to corpus generated using proposed IDFDDF method are relevant with the class of the data set.

V. CONCLUSIONS

The proposed method is another approach for feature selection for text classification. R8 of Reuters 21578 data set where used for experimentation. The proposed method, per forms well for feature selection. Hence the accuracy and performance in feature selection will certainly enhance by adopting the proposed methodology.
